BEZPROVANYAY, G. K.

A. G. Sukharov, and G. K. Bezprovanyay, Oborudovaniye litograficheskikh tochnits (Equipment of Litho-Offset Shops). "Izdast'o" Press.

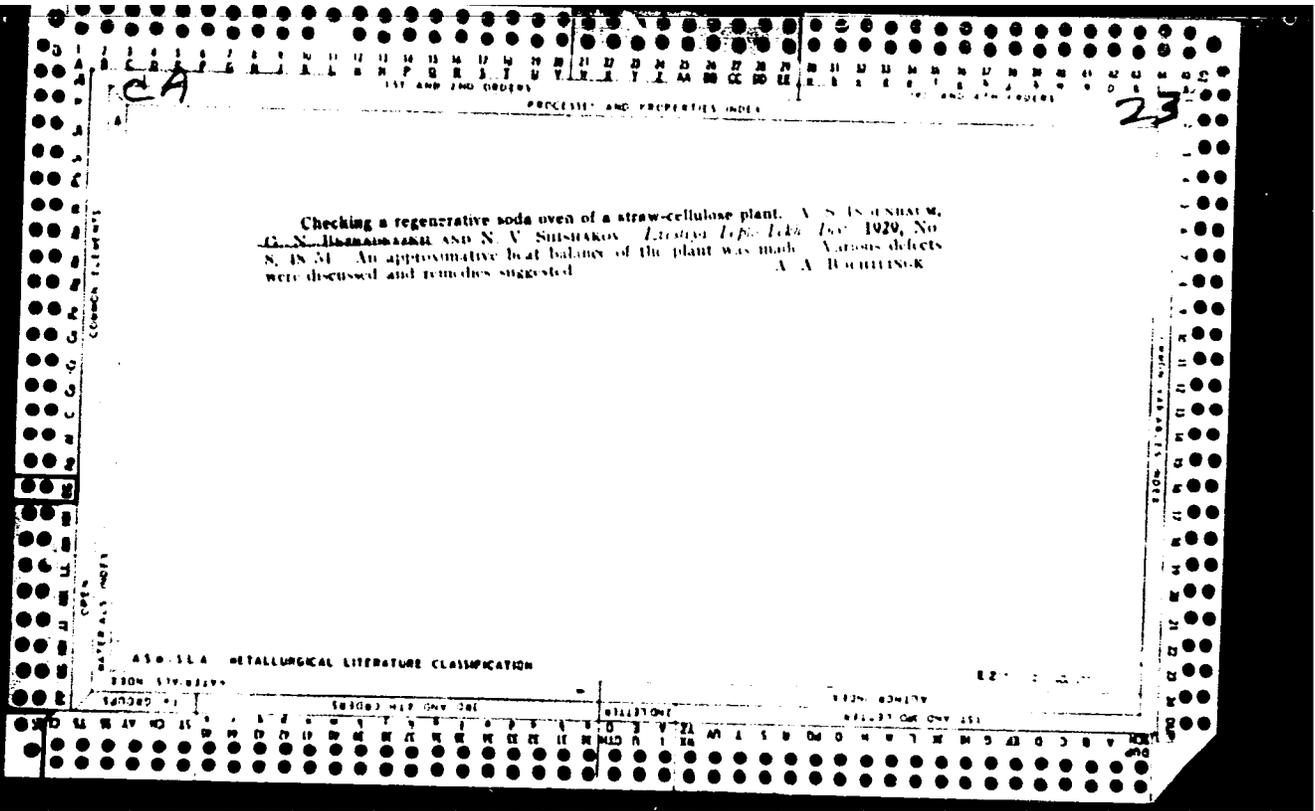

The booklet describes all presses, all types of casting equipment of offset printing shops and enterprises, and describes the principal models in detail, including all mechanics of the machines, and their interrelation with each of the types of printing equipment. The booklet also contains a section on the operation and maintenance of equipment, giving basic information on tending and repairing machines.

The booklet is intended for students of polygraphic technical schools.

BEZRADETSKIY, G. N.

*Chem* Alcohols from hydrocarbon synthesis reaction waters.  
 G. N. Bezradetskii and R. L. Melent'eva. *Trudy Vsesoyuzn. Nauch.-Issledovatel. Inst. Khim. i Zhidkogo Topliva*, GAZ 1954, No. 6, 90-104; *Referat. Zhur., Khim.* 1955, No. 2808. —The nature and quantities of alcs. found in the reaction water from the synthesis of hydrocarbons from CO and H over Fe, Fe-Cu, and industrial Co catalyst were studied. To ext. the alcs. the reaction waters were neutralized with a 10% alk. soln. to a neutral or weakly alk. reaction, and were then concd. by distn. The concd. neutral hydroxy compds. were then fractionated in a highly efficient column with 59 theoretical plates, tapping off individual alcs. A process is outlined for the concn. of the reaction water in a continuously operating installation. To obtain a 70% alc. concentrate the steam should be 96° and the reaction water fed at a rate of 0.37-0.44 ml./min./sq. cm. The  $n_D$  of the alc. concentrates, i.e. mw alcs., is 1.380-1.388. The fractionation in the column yielded MeOH, EtOH, PrOH, AmOH, and higher alcs. The alcs. were of tech. grade and required further purification. Six samples of reaction waters obtained by carrying out the synthesis reaction over various catalysts yielded the following alcs.: Fe catalyst MeOH 2.0-7.0, EtOH 48-62, PrOH 7.0-14.0, and higher alcs. 5-13%; Fe-Cu catalyst MeOH 13.0-25.0, EtOH 32-35, PrOH 8-15, and higher alcs. 8-10%; Co catalyst MeOH 13.6, EtOH 35, PrOH 12.8, and higher alcs. 19.8%.

**TITLE:**

An Electric Coal Level Indicator in an Adsorption Tower (Elektronnyy signalizator urovnya uglya v kolonne adsorbera)

**PERIODICAL:**

Priborostroyeniye, 1959, Nr 4, pp 28-29 (USSR)

**ABSTRACT:**

Such a device must comply with the following requirements: 1) The resistance  $R_s$  of the signal electrodes, at which the operation of the generator is stopped, must not exceed 100 ohms. 2) The second requirement arises from the stipulations of safety engineering: The potential between the signal electrodes must not exceed 1.5 v, and an rms value of 1.07 v for d. c. and a. c., respectively. 3) The device must provide for stable operation and the connection of leads with a length of 50 m must be possible (between the signalizer and the electrodes). In the Laboratory for Automation of the Kiyevskiy filial instituta Giprottransneft' (Kiyev Branch of the State Institute for the Design and Planning of Structures, Transportation and Storage in the Petroleum Industry) a level

Card 1/3

An Electric Coal Level Indicator in an Adsorption Tower

SOV/119-59-4-14/18

indicator complying with these conditions was developed and tested under laboratory conditions. The circuit of this signalizer consists of 2 oscillators with vacuum tubes of the type 6Zh4, of amplifier cascades with tubes 6N8 and of a supply unit. The device can be tuned by the following methods: 1) shunting of the oscillation circuit with an active resistance ( $\sim 20,000$  to  $100,000$  ohms). 2) Successive introduction of an active resistance  $R_d$  ( $\sim 30$  ohms) into the circuit of the feedback coil. 3) Introduction of a ferromagnetic core into the interior of the coil of the high-frequency transformer. It was readily seen from the experiments that the circuit can be tuned most simply by the second method. Automobile spark plugs with somewhat extended electrodes are best suited as signal electrodes. The performance of the oscillators can be controlled by tumblers. In this circuit electromagnetic d. c. relays of the type MKU-48 were used, which are supplied from a 220 v source. It is not advisable to supply this oscillator with a. c. The oscillator was d. c. fed through a germanium

Card 2/3

Tower

SOV/119-59-4-14/18

rectifier diode of the type DG-Ts27 and a filter element. This level indicator takes only about 30 w from the power supply. It is suited not only to the control of the coal level in an adsorption tower, but also for the control of other substances with an explosion hazard. Moreover it can be used as an element in circuits of automatic control. There are 2 figures.

TOPIC TAGS: internal combustion engine, engine fuel system

ABSTRACT: This Author's Certificate introduces an automatic float-type air and gas separator for the fuel system of an internal combustion engine. The unit contains a housing with a float which operates an air discharge valve when the fuel reaches a limiting level. Failures in the system are indicated by an alarm system controlled by contacts which are closed by the float through the valve rod when the fuel falls below the limiting level.

TITLE: Spectroscopic Determination of Beryllium Traces in Uranium

PERIODICAL: Zhurnal analiticheskoy khimii, 1961, Vol. 16, No. 1, pp. 57-59

TEXT: The present publication describes a method of determining  $10^{-6}\%$  of beryllium in uranium. The first step consists of separating the beryllium traces from the uranium. Of various known methods of separating beryllium from uranium, the chromatographic separation on a cationite using various complexing agents is the most promising (Refs. 14-17). The authors determined the optimum conditions for the separation. Separation is satisfactory on a KY-2 (KU-2) cationite with 0.25 mm grain size. Beryllium comes off the column with a sulfosalicylic acid solution, the most suitable rate of elution being 0.5 ml/min. The quantity of exchange resin used is of great significance. A 10-mm diameter column must contain at least 10 g of KY-2 (KU-2) resin in the air-dry state per 1 g of sample. One of the determining factors of separation is the pH of the wash-out solution which should be 3. Deviations are permissible only towards smaller values. The possibility of

completely separating was tested using uranium solutions containing between  $10^{-2}$  and  $10^{-3}$ % of beryllium. The results obtained were satisfactory (Tab. 1). To determine smaller quantities of beryllium, the latter not only must be separated from uranium, but also must be concentrated. Two series of beryllium determination experiments were carried out, the one using the fluorescence of beryllium, the other employing spectral analysis. The fluorescence method was found to be unsuitable. Basing on results obtained by spectroscopic analysis (Tab. 2), the authors suggest a combined method for determining beryllium in uranium down to  $10^{-6}$ % beryllium, consisting in chromatographic enrichment of beryllium and subsequent spectroscopic analysis. The time required for one analysis is  $\sim 40$  h. The error is  $\pm 20$ %. There are 2 tables and 17 references: 6 Soviet, 2 Dutch, 2 Swiss, 3 US, 1 Austrian, 1 Japanese, and 2 Czech. X

TITLE: Propagation of a pulse signal in the Epstein ionospheric layer

SOURCE: Leningrad. Universitet. Problemy difraktsii i rasprostraneniya voln, no. 5, 1966. Rasprostraneniye radiovoln (Radio wave propagation), no. 4, 71-84

TOPIC TAGS: signal propagation, ionospheric propagation, ionospheric electron density, ionospheric radio wave

ABSTRACT: The Epstein model of the ionosphere was used in the present study because large gradients in the dielectric constant are permissible and a unique solution can be obtained for the field over the entire region. The existence of an exact solution is shown for the problem of the propagation of a pulsed signal in an Epstein ionosphere, assuming that electron concentration is a continuous function of altitude. The effect of damping due to collisions is discussed briefly. The material of this article is part of a dissertation by L. I. Bezruchenko under the direction of G. I. Makarov. TITLE: Calculation of the Overhang of the End-windings of  
Commutator-machine Armatures (Raschet vyletov lobovykh  
chastey obmotok yakorey kollektornykh mashin)

PERIODICAL: Vestnik Elektromyshlennosti, 1958, . . . Nr 6,  
pp 68 - 69 (USSR).

ABSTRACT: When space is limited, it may be necessary to calculate the overhang of the end-windings of commutator-machine armatures before the complete section is designed. The existing approximate method is inaccurate and the complete geometrical calculation is laborious, whereas the method now recommended is quick and accurate. A formula is derived for the length of overhang, which consists of three parts, two in line with or parallel to the slot and the other sloping. A worked example is given. There are 2 figures.

TITLE: Technico-economic Indices of DC Traction Motors as a Function of the Rated Voltage (Tekhniko-ekonomicheskiye pokazateli tyagovykh dvigateley postoyannogo toka v zavisimosti ot nominal'nogo napryazheniya)

PERIODICAL: Izvestiya Vysshikh Uchebnykh Zavedeniy, Elektromekhanika, 1958, Nr 8, pp 78 -- 84 (USSR)

ABSTRACT: According to calculations and practical experience of manufacturers of traction motors, the saving in weight by using 6-pole motors as compared with using 4-pole motors varies between 700 and 900 kg, depending on the rating of the motor. In this paper, the author investigates the geometrical parameters of the motor, the influence of the thickness of the slot insulation on the degree of utilization of the active layer of the armature and also the weight and cost indices and the efficiency values. In his investigations the author considered motors of ratings of the order of 650 kW with voltages between 750 and 1500 V. The following conclusions are arrived at: for reducing to a minimum the weight of traction motors, the armature of the motor should have the smallest possible

Technico-economic Indices of DC Traction Motors as a Function of the  
Rated Voltage

diameter; the metal costs (ferrous and non-ferrous) of traction motors of a given power remain practically the same for motors of differing voltages; the insulation costs of a motor of a certain power rating change in proportion to the voltage. Therefore, the change in the costs of the motor of a given power rating at various voltages depends solely on the changes in the cost of the insulation. There are 3 figures, 2 tables and 3 Soviet references.

Induction heating of blanks of heat-resistant alloy  
E1437 for drop forging. I. I. Pevnuchko, Ya. M. Dityat-  
kovskii, and M. S. Aizikovich. *Metalloved. i Obrabotka*  
*Metal.* 1956, No. 4, 59-60. Blanks 52 mm. in diam. and  
187 mm. long were heated in an inductor 65 mm. in diam.  
and 1070 mm. long coatg. 99 turns of Cu tubing. The  
2500-cycle generator had a capacity of 160 kw. The blanks  
were to be heated to  $1100^{\circ} \pm 10$  with variations of not  
more than  $\pm 10^{\circ}$ . Insulating tubes of micaite, asbestos,  
and fireclay, 2, 3, and 6 mm. in diam., resp., were nested  
inside the inductor and outside of the blank being heated.  
The inductor was unsoldered at the center to permit the two  
halves to be connected in parallel and thus keep  $\cos \phi$  near 1.  
The surface temps. were detd. by using three suitably spaced  
Pt-PtRh thermocouples and a 4th couple was at the center,  
15 mm. in from one end. At a specific power of 0.031  
kw./sq. cm. and with the blank advanced  $\frac{1}{2}$  of the distance  
through the inductor every 33 sec., the blank reached  $1100^{\circ}$   
to within about 10 or 12" at the end of the inductor. The  
temp. at the center lagged about  $75^{\circ}$  behind the surface  
during most of the heating period, but within 3 sec. after  
removal of the blank from the inductor, the center temp.  
was nearly the same as that of the surface. The elec.  
energy for heating was 0.50 kw.hr./kg. The grain size of  
the blanks was 5 to 6 compared to the 3 to 4 grain size  
produced by conventional heating. A. C. Guy.

TITLE: Advanced Stamping Technology Employs Induction Heating  
(Peredovaya tekhnologiya shtampovki s primeneniym induktsionnogo nagreva)

PERIODICAL: V sb.: Novoye v kuznechno-shtampovochn. tsekhakh Leningrada  
Leningrad, 1958, pp 78-88

ABSTRACT: The employment of the method of induction heating of blanks in the forging shop made it possible to change over to a more rational technology involving simultaneous stamping of two forgings of the locking crown of a drum in a 1000-ton press with an insert die having two finishing impressions. The high economic efficiency of combining operations of stamping in a press with induction heating of blanks is pointed out. A computation of the economic indices of the new technology is presented and the layout of the working area is described; two induction-heating devices employed in the heating of blanks and hardening of the forging of the locking crown of a drum are also described.

TITLE: Induction Heating of Tubular Blanks From Ferromagnetic Materials

PERIODICAL: Kuznechno-shtampovochnoye proizvodstvo, 1960, No. 6, pp. 35 - 39

TEXT: The described experimental investigation has been carried out because of the high effectiveness of induction heating as a means for local heating necessary in bending and upsetting of tubular blanks. Tube blanks of "45" steel were used in the experiments with 90 mm in diameter, 250 mm long and a wall thickness of 18, 12 and 6 mm. The wall thickness (s) was selected corresponding to the penetration depth of electric current with a given frequency into heated steel ( $\delta_{op}$ , for " $\delta_{hot}$ ") at the Curie point (768°C). Maximum heating temperature was 1,250°C. The inductor length was taken equal to the blank length plus 2 blank diameters (Formula 1). The penetration value " $\delta_{hot}$ " for "45" steel is 12 mm. Heating was so controlled that in tubes with 18 and 12 mm wall thickness the hottest point was at 6 mm under the surface at a 2,500 c/s frequency. It was stated that in tube blanks with such a diameter and  $\delta_{hot}$  the heat distribution in the wall thickness can only be such as shown in Figure 4 when 2,500 c/s is used, and

Induction Heating of Tubular Blanks From Ferromagnetic Materials

heating of the surface alone is not possible at all. Surface heating would require a frequency of about 10,000 c/s, which is not economical. It was concluded that the heating time is the time needed to heat the point 2 to 1,250°C. Table 2 shows the investigation results, i.e., temperature drop in °C observed in pipe walls; heating time (t) in seconds; useful power transmitted into the blank ( $P_{usf}$ ) [Abstractor's note:  $P_{useful}$  is a translation of the Russian  $P_{наст}$  ( $P_{нагревания}$ ) in kw; full efficiency ( $\eta_u$ ) of the system inductor-blank; current consumption from 50-cycle network ( $A_c$ ) in kw/hour per kg. As can be seen, the efficiency value ( $\eta_u$ ) grows with diminishing pipe diameter at unchanging tube diameter to reach 0.95 or nearly the possible maximum at a wall thickness of 6 mm. This means that when the tube wall thickness equals half the current penetration depth or less, heat is being separated throughout the wall thickness simultaneously and the effect of heat conductivity on heating is fully eliminated, the heating time reduced, and hence the current losses reduced as well. The optimum heat and power values determined show that at  $\eta_u$  near the maximum (0.8 - 0.9) the minimum specific current consumption is 0.44 - 0.46 kw/hour per kg at an optimum temperature drop of 40°C in the tube wall. At such a temperature drop, the heat-

Induction Heating of Tubular Blanks From Ferromagnetic Materials

ing time for 90 mm diameter tubes is 137 sec for an 18 mm wall, 95 sec for 12 mm and 47 sec for 6 mm. To solve the problem for tubes of other diameters and current with other frequencies, the theory of similarity (Refs. 1, 4) can be used, and the change of the linear dimensions (outer tube diameter and wall thickness) expressed by equation  $x_1 = nx$  (7). Then,  $t_1 = n^2t$ ;  $f_1 = \frac{f}{n^2}$ ;  $P'_0 = \frac{P_0}{n}$ ; (8)

where  $x$  is the linear tube dimension in cm;  $t$  - heating time in sec;  $f$  - current frequency in c/s;  $P_0$  - specific power in kw/cm<sup>2</sup>;  $n$  - the similarity coefficient; and  $x, t, f, P_0$  are initial values, i.e., values known from experiments, and the same values with the index "1" are sought for. Blanks from material with other heat conductivity ( $\mathcal{L}$ ) will require the same heating time. Two practical problems are solved: 1) Finding  $n, s_1, t_1$  and  $f_1$  for a 180 mm diameter tube, and finding the heating time for a tube of "45" steel with an outer diameter of 9.0 cm and an inner diameter of 7.8 cm. TITLE: Energy consumption during the induction heating of titanium alloys for hot pressing

SOURCE: Kuznechno-shtampovochnoye proizvodstvo, no. 8, 1964, 37-38

TOPIC TAGS: pressing, titanium alloy, titanium alloy pressing, hot pressing, induction heating, energy consumption/alloy IMP2

ABSTRACT: Induction heating of such metals as titanium and its alloys, which are susceptible to absorption of gases at high temperatures, provides an opportunity for raising the productivity and quality of pressing operations. On the basis of experiments conducted with titanium alloy IMP2, the authors tried to determine the appropriate current frequency and to derive equations for induction coil efficiency, specific electrical energy consumption and specific power as functions of the blank diameter and temperature difference across the blank. In these experiments, blanks 25-70 mm in diameter were induction heated at a frequency of 2500 cycles/sec. The internal diameter of the induction coil was 65-100 mm, and heating was continued to 980C. Temperature changes and

Card 1/4

ACCESSION NR: AP4044285

distributions across the blank section, the temperature and consumption of induction coil cooling water, generator power, and other electrical parameters were recorded during the tests. The hot penetration depth of the heating current was computed from

$$\Delta = 5030 \sqrt{\frac{\rho}{\mu f}} = 1.26 \text{ cm} \quad (1)$$

where the mean resistivity of alloy IMP2 in the temperature range 20-980 C ( $\rho$ )

$= 1.57 \times 10^{-4}$  ohm-cm; the magnetic permeability  $\mu = 1$ ; and the current frequency  $f=2500$  cps. The findings of the investigation are shown in tables and graphs (see Fig. 1 in the Enclosure). The results showed that the useful specific power during induction heating of titanium alloy blanks having diameters of 25 - 70 mm, and for various temperature differences across the cross section of the blanks, lies in the range 0.007-0.07 kW/cm<sup>2</sup>; the average specific consumption of useful energy lies in the range 0.160-0.130 kWh/kg, so that the mean specific consumption of electrical energy, assuming correct distribution and a full load on the converters, amounts to 0.3-0.4 kWh/kg. It is concluded that the specific energy

Card 2/4

ACCESSION NR: AP4044285

consumption during induction heating is less for titanium than for carbon steel, and that the average efficiency of the whole system is 0.45-0.47 for the heating of titanium alloys. Orig. art. has 3 figures, 2 tables, and 4 formulas.
